The model

Nonobservable ergodic diffusion process (X_t) with

- values in \mathbb{R}^d ;
- observations (Y_t) from \mathbb{R}^ℓ ;
- initial distribution μ_0 (of X_0) known **with some error**.

The question

Is this error forgotten by the optimal filtering algorithm in the long run?

A question for discussion

What does it mean "the optimal filtering algorithm" ?

Two related questions

- Blackwell: Is a stationary measure unique (only Q)?
- We: Is the filter stable?

Fact

Stability of filter \Rightarrow uniqueness of stationary measure.
(A. Budhiraja, H.J.Kushner).

A.Budhiraja (2008) - link between different properties of the nonlinear filter process:

- Stability of the filter with respect to initial conditions
- Uniqueness of the invariant measure of the filter
- "Finite memory" property of the filter

Counterexample for the proof

an **ergodic** Markov process X_t with

- state space $\mathbb{S} = \{1, 2, 3, 4\}$;
- transition intensity matrix:

$$\Lambda = \frac{1}{2} \begin{pmatrix} -1 & 1 & 0 & 0 \\ 0 & -1 & 1 & 0 \\ 0 & 0 & -1 & 1 \\ 1 & 0 & 0 & -1 \end{pmatrix};$$

- **noiseless** observation: $\mathbf{Y}_n = \mathbf{1}_{X_n=1} + \mathbf{1}_{X_n=3}$.

Result: the answer is "False". Also, filter is unstable, the invariant measure of the filtering process is not unique.

Nothing is clear

Comparison of total variation distance and Birkhoff distance

(Christophe Leuriden, private communication)

- For normalized measures μ and ν :

$$\|\mu - \nu\|_{TV} \leq \rho(\mu, \nu)$$

- The converse statement does not hold.

Example

$$q_\mu(x) = \mathbf{1}(x \in [-1/2, 1/2])$$

$$q_\nu(x) = \frac{1}{2} \cdot \mathbf{1}(|x| \in [\varepsilon, 1/2]) + C \cdot \mathbf{1}(x \in [-\varepsilon, \varepsilon])$$

Then $\|\mu - \nu\|_{TV} = 1 - 2\varepsilon$, $\rho(\mu, \nu) = \ln(1 + \frac{2}{\varepsilon})$

Changing of measure

Using **Girsanov's transformations and integration by parts** we change the measure:

$$\frac{dP}{d\hat{P}} = \exp\left[\sum_{k=1}^{[t]} h^*(X_k)(Y_k - Y_{k-1}) + h^*(X_t)(Y_t - Y_{[t]})\right. \\ \left. + \frac{1}{2} \int_0^t c(X_s, Y) ds\right],$$

with

$$c(s, x, Y) = \|(Y_s - Y_{[s]})^* \nabla h(x)\|^2 - 2(Y_s - Y_{[s]})^* \Delta h(x) - \|h\|^2(x).$$

- The density has a special form:

$$L_n = \prod_{k=1}^n \exp[h^*(X_k)(Y_k - Y_{k-1}) + \frac{1}{2} \int_{k-1}^k c(X_s, Y) ds],$$

- The transformed process (X, Y) (w.r.t \hat{P}) is nice:

$$\begin{cases} dX_s = (b(X_s) - (Y_s - Y_{[s]})^* \nabla h(X_s)) ds + dW_s, \\ dY_s = dB_s, \end{cases}$$

with independent W and B .

- We are in the situation "Conditional distribution, particular case"
- Now we can choose the continuous (w.r.t Y) version of the conditional measure.
- Hence, we can use the first boundary problem.

Our goal is to prove the following inequality:

The main inequality

$$E_{\mu_0} \|\bar{\mu}_t(\cdot; \mu_0) - \bar{\mu}_t(\cdot; \nu_0)\|_{TV} \leq C \sum_{\delta \in \Delta} \kappa_R^{\#1(\delta)} E_{\mu_0, \nu_0} e_{[t]}^{Y; \delta; \mu_0, \nu_0},$$

$$\kappa_R := \frac{C_R^2 - 1}{C_R^2 + 1} < 1,$$

$$C_R = \sup_{|x|, |\tilde{x}|, |z|, |\tilde{z}| \leq R} \frac{u(0, x, \tilde{x})}{u(0, z, \tilde{z})}$$

with $u(s, x, \tilde{x})$ - the solution of the first boundary problem.

part 2

We estimate the first term

$$\begin{aligned} E_{\mu_0} \left(E_{\mu_0} \left(\mathbf{1}(\# \mathbf{1}(X)_R < \frac{1 + \varepsilon}{2} n) \mid Y \right) \right) \\ = E_{\mu_0} \left(\mathbf{1}(\# \mathbf{1}(X)_R < \frac{1 + \varepsilon}{2} n) \right). \end{aligned}$$

we can use the "Separation of pairs, II".

Next, we estimate the other term, using the **absolute continuity of the initial measures**:

$$\begin{aligned} & E_{\mu_0} \left(E_{\nu_0} \left(\mathbf{1}(\#\mathbf{1}(\tilde{X})_R < \frac{1+\varepsilon}{2}n) \mid \tilde{Y} \right) \Big|_{\tilde{Y}=Y} \right) \\ & \leq C_2 E_{\nu_0} \left(E_{\nu_0} \left(\mathbf{1}(\#\mathbf{1}(\tilde{X})_R < \frac{1+\varepsilon}{2}n) \mid \tilde{Y} \right) \Big|_{\tilde{Y}=Y} \right) \\ & = C_2 E_{\nu_0} \left(\mathbf{1}(\#\mathbf{1}(\tilde{X})_R < \frac{1+\varepsilon}{2}n) \right), \end{aligned}$$

Again, the **Separation of pairs, II**.

Sketch of the proof,
part 2

How can we prove the main inequality?

Define new **linear** operators on the space of non-normalized measures on \mathbb{R}^{2d}

$$\mu_t(A \times B; (\mu_0, \nu_0)) = \int_{\mathbb{R}^{2d}} Q_t(x_0, \tilde{x}_0; A \times B) d\mu_0(x_0) d\nu_0(\tilde{x}_0).$$

with the same kernel Q_t :

$$Q_t(x_0, \tilde{x}_0; A \times B) = \widehat{E}_{x_0, \tilde{x}_0}(\mathbf{1}(X_t \in A, \tilde{X}_t \in B) \times L_t(X, Y)L_t(\tilde{X}, \tilde{Y}) \mid \mathcal{F}_t^{Y, \tilde{Y}}) \Big|_{\tilde{Y}=Y}$$

We have

$$\bar{\mu}_t(A \times B; (\mu_0, \nu_0)) = c_t^{\mu_0} c_t^{\nu_0} \mu_t(A \times B; (\mu_0, \nu_0))$$
